Rules of Exponents

Example: $5^2$
- base: 5
- exponent: 2
- power: 2nd
- read: five squared or five to the second power

Exponents are used in many algebra problems, so it's important that you understand the rules for working with exponents. Let's go over each rule in detail, and see some examples.

**Rules of 1**

There are two simple "rules of 1" to remember.

First, any number raised to the power of "one" equals itself. This makes sense, because the power shows how many times the base is multiplied by itself. If it's only multiplied one time, then it's logical that it equals itself.

Secondly, one raised to any power is one. This, too, is logical, because one times one times one, as many times as you multiply it, is always equal to one.

$$x^1 = x$$
$$3^1 = 3$$

$$1^m = 1$$
$$1^4 = 1 \cdot 1 \cdot 1 \cdot 1 = 1$$

**Product Rule**

The exponent "product rule" tells us that, when multiplying two powers that have the same base, you can add the exponents. In this example, you can see how it works. Adding the exponents is just a short cut!

$$x^m \cdot x^n = x^{m+n}$$
$$4^2 \cdot 4^3 = 4^{2+3} = 4^5$$

*Note:* $4^2 \cdot 4^3 = (4 \cdot 4) \cdot (4 \cdot 4 \cdot 4) = 4^5$

**Power Rule**

The "power rule" tells us that to raise a power to a power, just multiply the exponents. Here you see that $5^2$ raised to the 3rd power is equal to $5^6$.

$$(x^m)^n = x^{mn}$$
$$(5^2)^3 = 5^{2 \times 3} = 5^6$$

[This also makes sense. Note: $(5^2)^3=5^2 \cdot 5^2 \cdot 5^2 = (5 \cdot 5) \cdot (5 \cdot 5) \cdot (5 \cdot 5) = 5 \cdot 5 \cdot 5 \cdot 5 \cdot 5 = 5^6$]
**Quotient Rule**

The quotient rule tells us that we can divide two powers with the same base by subtracting the exponents. You can see why this works if you study the example shown.

\[
\frac{x^m}{x^n} = x^{m-n}, \quad x \neq 0
\]

\[
4^5 \div 4^2 = \frac{4^5}{4^2} = \frac{4 \cdot 4 \cdot 4 \cdot 4 \cdot 4}{4 \cdot 4} = 4^{5-2} = 4^3
\]

**Zero Rule**

According to the "zero rule," any nonzero number raised to the power of zero equals 1.

\[
x^0 = 1, \quad x \neq 0
\]

\[
37^0 = 1
\]

**Negative Exponents**

The last rule in this lesson tells us that any nonzero number raised to a negative power equals its reciprocal raised to the opposite or positive power.

\[
x^{-n} = \frac{1}{x^n}
\]

\[
4^{-2} = \frac{1}{4^2} = \frac{1}{16}
\]

\[
\left( \frac{4}{5} \right)^{-3} = \left( \frac{5}{4} \right)^3 = \frac{5^3}{4^3} = \frac{125}{64}
\]

Note also: any nonzero number raised to a positive power equals its reciprocal raised to the opposite or negative power.

\[
4^2 = \frac{1}{4^{-2}}
\]
Study these examples to see a few common errors that students make when working with exponents.

1. The exponent next to a number (or variable) applies only to that number (or variable) unless there are parentheses indicating otherwise.

\[-4^2 \neq (-4)^2\]
\[-\cdot 4 \cdot 4 \neq (-4)(-4)\]
\[-16 \neq 16\]

Note: \(-4^2 = -\cdot 4 \cdot 4\) (or \(-1 \cdot 4 \cdot 4\)) = -16

1. The product rule \((x^m \cdot x^n = x^{m+n})\) only applies to expressions with the same base.

\[4^2 \cdot 2^3 \neq 8^{2+3}\]
\[(4)(4) \cdot (2)(2)(2) \neq 8^5\]
\[128 \neq 32,768\]

2. The product rule \((x^m \cdot x^n = x^{m+n})\) only applies to the product, not the sum, of two numbers.

\[2^2 + 2^3 \neq 2^{2+3}\]
\[(2)(2) + (2)(2)(2) \neq 2^5\]
\[4 + 8 \neq 32\]
\[12 \neq 32\]
